

UNIT 2: Cells Chapter 3: Cell Structure and Function

I. Cell Theory (3.1)

A. Early studies led to the development of the cell

1. Discovery of Cells

1

b. **Anton van Leeuwenhoek** (1674)made powerful single lens microscope. One of first to look at and describe living cells

2. More was learned as **microscopes** were improved

B. Development of Cell Theory

1. Matthias Schleiden (1838)- proposed all plants made of cells

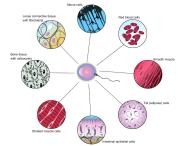

2. **Theodor Schwann** (1839)- after talking with Schleiden, concluded that all **animals** were also <u>composed of cells</u>

3. **Rudolf Virchow** (1855)- Proposed that <u>all</u> <u>cells come</u> <u>from pre-existing cells</u>

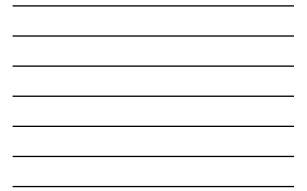

4. Accumulated research summarized as **Cell Theory** (one of first unifying concepts in biology)

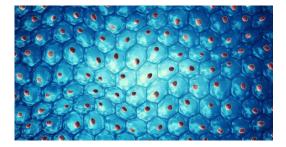

b. All existing **cells** are <u>produced</u> by other living cells 0 0 DNA 0 cell elongation

c. The cell is the most basic unit of life

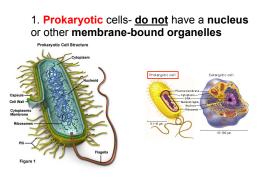

C. All cells share certain characteristics

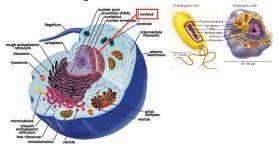

- Cells tend to be <u>microscopic</u>
 All cells are <u>enclosed</u> by a n
 All cells are <u>filled</u> with cytoplasm membrane

D. Cells can be separated into two broad categories

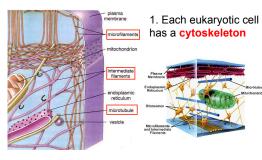

2. Eukaryotic cells- <u>have</u> a nucleus and other **membrane bound organelles**. May be single or multicellular organisms

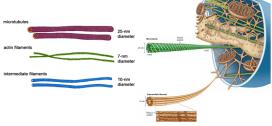

II. Cell Organelles (3.2)

A. Cells have an internal structure

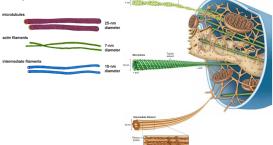

a. <u>Supports</u> and <u>shapes</u> the cell and helps <u>position</u> and <u>transport</u> organelles (**microtubules**) Made of thick, strong spirals of thousands of subunits. Those subunits are made of the **protein** called **tubulin**.

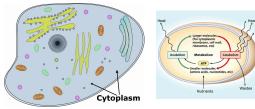

- b. Provides <u>strength</u> (intermediate filaments)
 c. Helps cells <u>move</u> and <u>divide</u> (microfilaments)
- c. Helps cells <u>move</u> and <u>divide</u> (microfilaments) Made of two intertwined strands of a globular protein called actin

2. cytoplasm- important contributor to cell structure

a. In eukaryotes, it fills space between nucleus and cell membrane

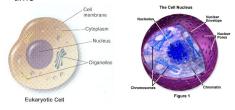

- b. Made up mostly of water
- c. Many chemical reactions occur in cytoplasm

B. Nucleus- storehouse for genetic material

- 1. Two major demands on nucleus
 - a. Protects DNA

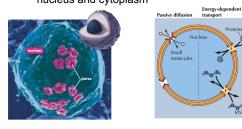

b. DNA must be available for use at proper time

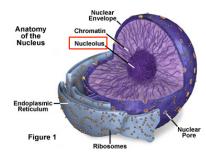

2. Nucleus surrounded by $\underline{\text{double membrane}}$ called nuclear envelope

a. Nuclear membrane pierced with holes called **pores**.

b. Allows large molecules to pass between nucleus and cytoplasm

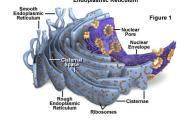

3. Contains nucleolus- makes ribosomes

C. Enodplasmic Reticulum (ER)

1. Interconnected network of thin **folded membranes**

2. Proteins and lipids are produced in ER

3. <u>Two types</u> of Endoplasmic Reticulum

 a. Rough ER- studded with ribosomes-makes proteins and lipids
 b. Smooth ER- no ribosomes on surface.
 Makes lipids and helps break down drugs and alcohol

Smooth endoplasmic reticulum

Smooth ER-

D. Ribosomes -composed of RNA and proteins

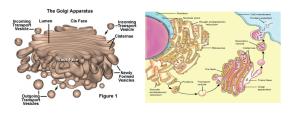

- 1. Site of protein production
- 2. Some bound to Rough ER and others suspended in cytoplasm

E. Golgi Apparatus- cells "post office"

1. Closely layered stacks of membrane-

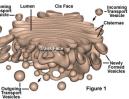

- enclosed spaces
- 2. <u>Packages</u> proteins (some stored for later use)
- 3. Sorts and delivers proteins

F. **Vessicles**- stores separate reactants for various chemical reactions

- 1. Membrane bound sacs
- 2. <u>Transport</u> materials from place to place (or for secretion)
- 3. Generally short lived and formed and
- recycled as needed The Golgi Apparatus

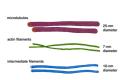

Microtubules are responsible for a variety of <u>cell</u> <u>movements</u>, including :

•Intracellular **transport** and positioning of membrane vesicles and organelles

•The separation of chromosomes at mitosis

•The beating of **cilia** and **flagella**. Movement along microtubules is based on the action of **motor proteins** that utilize energy

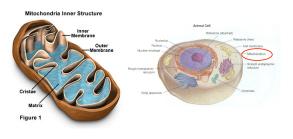

proteins that utilize energy derived from ATP hydrolysis to produce force and movement

 motor proteins: kinesins and the dyneins

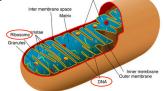

G. Mitochondria- cells "powerhouse"

Supply energy to cell
 Bean-shaped with two membranes

3. Series of chemical reactions inside folded inner folds converts food into usable energy for cell 4. Thought to have been originally free- living prokaryote because contain their own **ribosomes** and DNA.

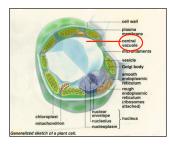

5. Mitochondrion has its own independent genome that shows substantial similarity to bacterial genomes

H. Vacuole- fluid-filled storage sac

1. Stores water, food molecules, inorganic ions, and enzymes.

2. Plants contain large, central vacuole

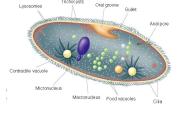

a. Takes up most of space in plant cell b. Filled with water and strengthens the

cell and helps to support plant

c. Plants rely on turgor pressure to maintain rigidity

3. Animal cells contain many small vacuoles

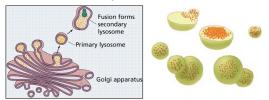

I. Lysosome- "suicide sacs"

a. membrane organelle containing enzymes b. Defend cell from invading bacteria and viruses

c. Break down damaged and worn-out cell parts

d. Not found in plant cells

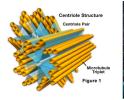

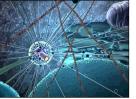

J. Centrosome and Centrioles

1. Small region of cytoplasm that produces microtubules.

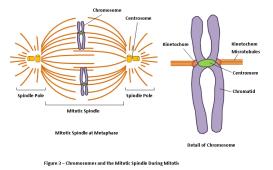

2. In <u>animal cells</u>, contains two small structures called **centrioles**.

a. cylinder-shaped organelles made of short microtubules.

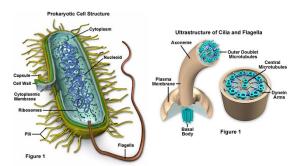

b. Help in cell division in animal cells

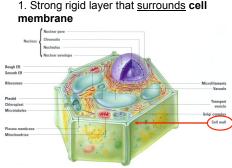

c. Form cilia and flagella

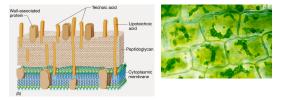

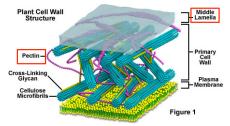

2. Provides protection, support, and shape to cell

3. Cell wall composition varies a. plants- **cellulose**

- b. fungi-**chitin**
- c. bacteria- peptidoglycan

 The middle lamella is a pectin layer which cements the cell walls of two adjoining cells together.
 Pectin is a structural heteropolysaccharide contained in the primary cell walls of terrestrial plants.

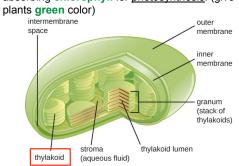

L. Chloroplasts- carries out photosynthesis 1. Highly compartmentalized organelle with outer and inner membranes.

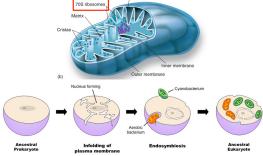

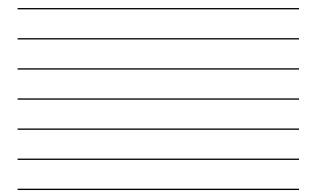

2. Contain **thylakoids** (disc-shaped sacs) with lightabsorbing **chlorophyll** for <u>photosynthesis</u>. (give plants **green** color)

3. Also thought to be free-living prokaryote originally because also contain own **ribosomes** and **DNA**

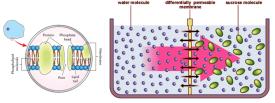

III. Cell Membrane (3.3)

A. Forms <u>boundary</u> between cell and outside environment.B. Controls passage of materials into and out

B. Controls passage of materials into and out of cell. Is **selectively permeable** (allows some things but not others) Helps to maintain

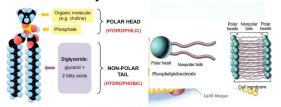

the cells homeostasis

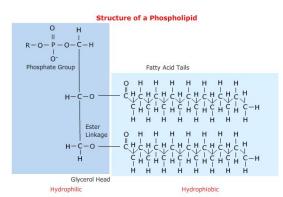

C. Consists of **double layer** of **phospholipids** interspersed with other molecules (proteins and carbohydrates)

1. Phospholipid- molecule composed of <u>3 basic parts</u>

a. phosphate and glycerol form "head" b. fatty acid forms "tail"

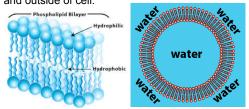

c. forms **polar** molecule ("head" hydrogen

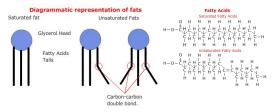

bonds to water molecules, and "tail" does not) d. **Double layered** membrane had "heads" on outside and "tails" on inside.

2. Forms **double layer** because of water on inside and outside of cell.

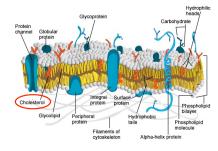

3. The length and the <u>degree of unsaturation</u> of fatty acid chains have a profound effect on membrane fluidity

4. **Unsaturated fatty acids** create a <u>kink</u>, preventing the fatty acids from packing together as tightly

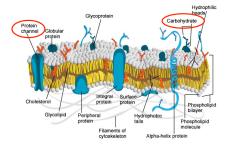

E. Other molecules are embedded with the phospholipid layers

1. Cholesterol molecules strengthen cell membrane

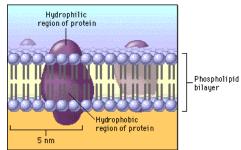

2. **Proteins** extend through membrane and form channels

3. **Carbohydrates** attached to proteins act like "identification tags"

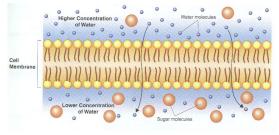

4. Fluid Mosaic Model- describes arrangement of molecules in cell membrane. Flexible "fluid like" lipid embedded with "mosaic" of other molecules.

F. Molecules <u>cross</u> membrane in several ways 1. Some methods of transport require **energy**

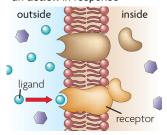

1. Some methods of transport require **energy** and some do not.

2. Depends molecules **size**, **polarity**, and **concentration** inside versus outside.

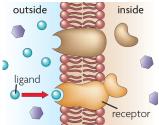

G. Cell membrane contains receptors that help transmit signals across membrane

- Made of proteins
 It <u>detects</u> a signal molecule and <u>performs</u> an action in response

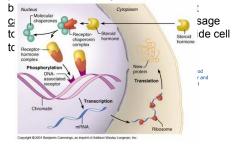

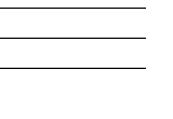

- 3. Receptors bind to molecules called ligands. a. When bind, they change shape
 - b. This changed shape affects how receptor interacts with other molecules

4. Two types of receptors

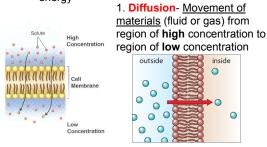

a. Intracellular receptors- (means "within" cell)- can interact with DNA and start production of certain proteins

IV. Diffusion and Osmosis (3.4)

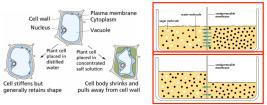

A. <u>Passive transport-</u> allows cell to move materials across cell membrane without using energy

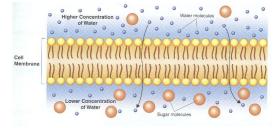

a. **Concentration gradient-** used to describe areas of high and low concentration.

b. When movement makes concentration
equal- reaches dynamic equilibrium
(Molecules still continue to move- dynamic)
c. Diffusion plays important role in movement
of carbon dioxide and oxygen molecules

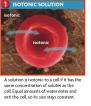

2. Osmosis- Diffusion of water molecules

a. <u>Three</u> terms used to describe the amount of **dissolved particles** in cell <u>compared</u> to **amount of water** (terms are comparisons)

1). Isotonic- same concentration of dissolved materials (water moves in and out at equal rate) 2). Hypertonic- solution has higher concentration of dissolved materials (Water concentration higher in cell than outside- water moves out of cell

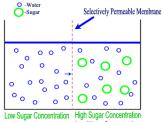

3). Hypotonic- Solution has lower concentration of dissolved materials (water moves into the cell)

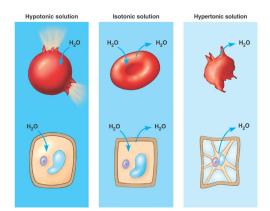

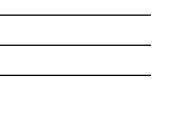

A hypotonic solution has fewer s than a cell. Overall, more water e a cell in hypotonic solution, caus the cell to expand or even burst.

Osmosis

Low Sugar Concentration High Sugar Concentration High Water Concentration Low Water Concentration

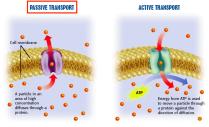

B. Facilitated diffusion- larger molecules can still diffuse through openings formed by transport proteins

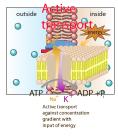

- 1. Still form of **passive transport**
- 2. Many types of transport proteins- most

allow only certain molecules to travel into cell

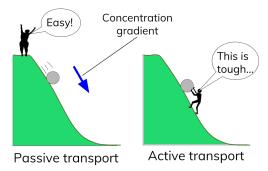

V. Active Transport, Endocytosis, and Exocytosis $\left(3.5\right)$

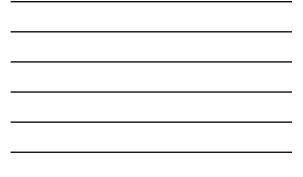

A. Active Transport- requires energy by cell to move materials in or out of cell.

1.Can use transport proteins to move molecules <u>against</u> concentration gradient (from low to high)

2. Use energy from **ATP** molecule

B. **Endocytosis**- Movement of liquids or large molecules **into** a cell by <u>engulfing</u> them in a membrane

1. Phagocytosis- "cell eating"

- a. Key role in **immune** system (white blood cells)
- b. Cell membrane make "<u>pocket</u>" around material

- 2. Exocytosis- opposite of endocytosis
 - a. Release of substances from cell
